Lecture 6, part I: More on SQL

October 8, 2004

Lecturer: Rasmus Pagh
Part I: More on SQL
- Subqueries in SQL.
- Authorization and privileges in SQL.
- Views in SQL.

Part II: OLAP and data cubes (next slide set)
- Information integration (e.g. data warehousing).
- OLAP.
- Data cubes and ROLAP.
In this lecture I will assume that you remember:

- The SQL concepts needed to solve the first hand-in:
  - Projection and selection using SELECT–FROM–WHERE.
  - SELECT–FROM–WHERE involving multiple relations.
Next: Subqueries in SQL
Until now, you have seen SQL queries of the form

```
SELECT <list of attributes>
FROM <list of relations>
WHERE <condition>
```

What we haven’t used is that:

- In any place where a relation is allowed, we may put an SQL query (a **subquery**) computing a relation.

- In any place where an atomic value is allowed, we may put an SQL subquery computing a relation with one attribute and one tuple.
Instead of just relations, we may use SQL queries in the FROM clause of SELECT-FROM-WHERE.

If we need a name for referring to the relation computed by the subquery, a tuple variable is used.

Subqueries should always be surrounded by parentheses.
Subqueries producing scalar values

When a query produces a relation with one attribute and one tuple, it can be used in any place where we can put an atomic (or scalar) value.

Semantics:

In places where an atomic value is expected, SQL regards a relation instance containing one atomic value $x$ to be the same as the value $x$.

If such a subquery does not result in exactly one tuple, it is a run-time error, and the SQL query cannot be completed.
Subqueries in conditions

One common use of subqueries is in the WHERE part of SELECT-FROM-WHERE. There are several operators in SQL that apply to a relation \( R \) and produce a boolean result:

- **EXISTS** \( R \) is true if and only if \( R \) is not empty.
- **s IN** \( R \) is true if and only if \( s \) is a tuple in \( R \).

If \( R \) is **unary** (has just one attribute):

- **s > ALL** \( R \) is true if and only if \( s \) is greater than all values in \( R \).
- **s > ANY** \( R \) is true if and only if \( s \) is greater than some value in \( R \).

...and similarly for other comparison operators (\(<, \geq, \leq, <>\)).
Correlated subqueries

Sometimes a subquery depends on (is correlated with) tuple variables/relations of the surrounding SELECT-FROM-WHERE.

**Semantics:**

The query is evaluated once for each binding of tuple variables in the surrounding SELECT-FROM-WHERE.

**Scoping rule:**

In case several tuple variables/relations have the same name $x$, an occurrence of $x$ refers to the closest such tuple variable/relation.
Semantics of SELECT-FROM-WHERE

SELECT *
FROM E1 V1, E2 V2, ..., Ek Vk
WHERE <condition>

1. Determine the values of E1, ..., Ek (which are subqueries or relations).
2. Form all possible combinations of tuples V1, ..., Vk, where V1 comes from E1, etc:
   (a) For each combination determine if <condition> is true.
       This may involve computing subqueries. If (attributes from) one of V1, ..., Vk is referred to in a subquery and is not a tuple variable in the subquery, we substitute in the appropriate value.
   (b) If the condition is true, we output the combination of V1, ..., Vk.
Problem session (5 minutes)

What does the below SQL query compute?

```sql
SELECT title, year
FROM Movie
WHERE EXISTS (SELECT *
    FROM Movie M2
    WHERE Movie.year = year + 1
    AND EXISTS (SELECT *
        FROM Movie M3
        WHERE M2.year = year + 1));
```

Tip: Read from inside out.
Next: Authorization and privileges in SQL
Because databases often have many users, not all of which are allowed to do any database operation, SQL has an **authorization** system.

Every user (called a **module** in case the user is a program) has certain rights, or **privileges**, to access and modify database elements. The basic privileges are:

```
SELECT, INSERT, DELETE, UPDATE
```

It is possible to have privileges for certain attributes in a relation, e.g., a secretary might have the `UPDATE(address, city)` privilege for relation with customer information.
Basics of managing privileges:

- If a user defines a new schema, she has all possible privileges for the tables (and other database elements) of that schema.
- Users may grant ("copy") privileges of their own to other users.
- Being able to grant a privilege is a special privilege in itself that can be passed on.

Syntax for granting privileges:

```sql
GRANT <privilege list> ON <database element>
TO <user list> [WITH GRANT OPTION]
```
Granted privileges can be withdrawn (or **revoked**) by a user at any time.

**Basics of revoking privileges:**

- Privileges given without the GRANT OPTION can simply be removed.
- Otherwise we would like to revoke any privilege in the database that is *only possible because of the privilege that was revoked*.
- What happens when revoking is *independent* on the order in which privileges were given.

**Syntax for revoking privileges:**

```
REVOKE <privilege list> ON <database element>
FROM <user list> CASCADE
```
Grant diagrams

To control revoking, the DBMS maintains a grant diagram (also called an authorization graph) with:

- One node for each privilege of each user.
- Arrows showing which privileges and users are behind each privilege.

Grant privileges due to ownership of a database element are indicated by **, and other grant privileges are indicated by *.

[Figure 8.26 shown on slide]
[Figure 8.27 shown on slide]
[Figure 8.28 shown on slide]
[Figure 8.29 shown on slide]
Consider the grant diagram of Fig. 8.26. Which privileges does Sisko have after the changes caused by user janeway running the following three SQL commands?

REVOKE SELECT ON Studio FROM picard CASCADE;
REVOKE INSERT ON Studio FROM kirk CASCADE;
GRANT INSERT(name) ON Studio TO kirk WITH GRANT OPTION;

What if the two last commands were swapped?
Next: Views in SQL
**Views** are queries that have been given a name.

Syntax for declaring a view:

```
CREATE VIEW <name of view> AS <SQL query>
```

We may use the name of a view in SQL expressions, as a *shorthand* for the corresponding query.
• Views are elements of the database schema, just like relation schemas.
• Privileges to access a view are handled just like privileges for relations.
• The privileges to perform the query must be held by the user who defines the view, but not necessarily by users accessing the view.
• Sufficiently simple views can be modified, meaning that the modifications are passed on to the underlying relations.
**Materialized views** are views that are physically stored, i.e. stored relations that are results of queries.

Syntax for declaring a materialized view in Oracle:

```
CREATE MATERIALIZED VIEW <name of view>
AS <SQL query>
```

Differences from an ordinary view:

- Allows faster access, as the query result is always computed.
- Needs to be updated when the underlying relations change.
As a minimum, you should after this week:

- Be able to understand and form SQL expressions using several levels of subqueries.
- Be able to define and use views in SQL.
- Understand the mechanism for granting and revoking privileges in SQL.
